

# Helical Ramp Inside Funnel Emitter (12-inch tall variant)

Emitter: stainless sheet funnel, black ceramic coating inside/outside. Coax increases gas wall contact without choking buoyant flow  
Internal helical ramp inside 24"→3" funnel (12" tall)

## Why the helical ramp transfers more plume energy into the walls

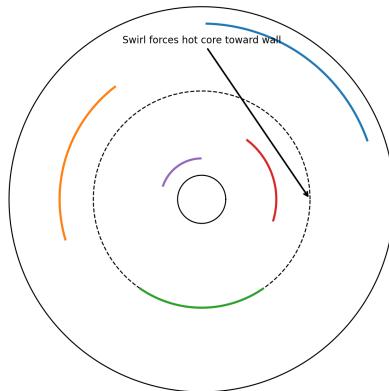

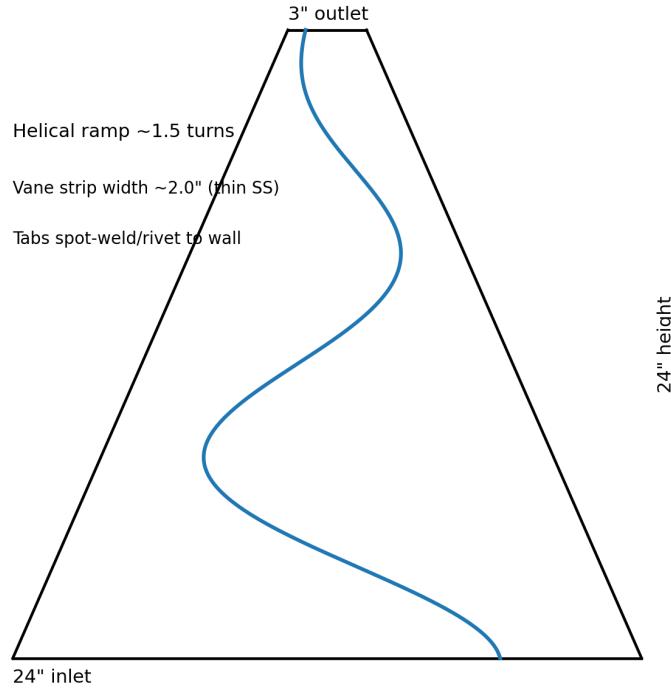

- 1) Swirl pushes the hot plume core outward (centrifugal pressure gradient), increasing wall wetting.
- 2) The ramp trips turbulence and repeatedly re-develops the boundary layer → higher internal  $h_{in}$ .
- 3) Wall contact increases without a tight maze; the open core preserves buoyant flow (low  $\Delta P$ ).
- 4) With black ceramic outside, more of the absorbed wall heat exits as IR to occupants.

## Manufacturing concept (thin stainless)

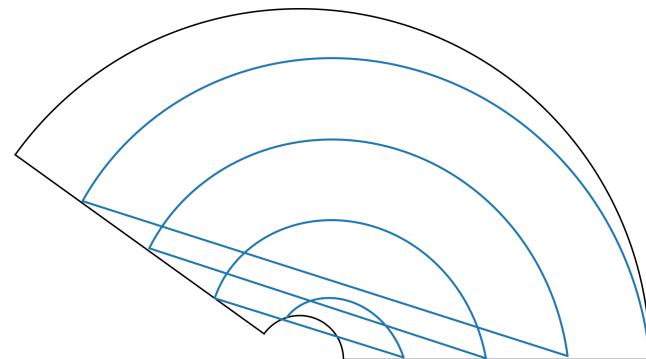

- A) Cut the funnel shell as an annular-sector flat pattern; roll and seam-weld (or rivet + seal).
  - 12" tall: slant height  $s \approx 15.9"$ ; sector angle  $\theta \approx 237.1^\circ$
  - Developed radii: outer  $\approx 18.2"$ , inner  $\approx 2.3"$
- B) Cut a vane strip ( $\approx 2"$  wide) with tabs every  $\sim 2\text{--}3"$ ; pre-form curvature.
- C) Install vane so it makes  $\sim 0.8$  turns over 12"; attach tabs to wall; keep blockage modest ( $<\sim 15\text{--}20\%$ ).
- D) Add an adjustable top damper (annular ring) to tune outlet effective area around the 3" target.

# Helical Ramp Inside Funnel Emitter (24-inch tall variant)

Emitter: stainless sheet funnel, ~~black ceramic coating inside/outside. Coats increase gas wall contact without choking buoyant flow~~  
 Internal helical ramp inside 24"→3" funnel (24" tall)

Top view (concept): helix drives rotation + wall contact

Flat pattern: annular sector ( $\theta \approx 144.3^\circ$ )  
 Developed radii: outer = 29.9 in, inner ≈ 3.7 in  
 Helical ramp becomes a straight path in the developed sheet

## What the extra height buys you

- More residence time + more wall area: higher extraction potential before exhaust leaves.
- You can run ~1.5 turns (gentle pitch) while keeping passages open.
- Lower risk of a 'hot core' shooting through; more uniform wall temperature.
- Tradeoff: taller emitter is visually larger; must still avoid over-restricting the outlet.

## Key design rules to avoid choking

- 1) Keep a clear axial flow path (open core). Avoid tight 'maze' passages that require a fan.
- 2) Use gentle vane pitch; target swirl, not blockage. Thin strip, small angle of attack.
- 3) Provide an adjustable damper with a safe minimum opening to prevent bypass around the emitter.
- 4) Validate with one measurement: exhaust temperature at the outlet + surface temperature with IR gun/thermocouples.
